8 Bit ALU

Nolan Kessler, Maxwell Fabian, John O'Connor

June 7, 2026

Video Link: ADD HERE

1 8 Bit ALU Functional Description

This 8 bit ALU accepts two 8 bit operands A and B, along with a 3 bit opcode (OP). The state of the ALU is controlled by an active high enable pin (EN), and can be reset using the active low reset pin (RST_N). As this ALU supports sequential operations which may take more than one clock cycle, the CLK input must be connected to a clock signal. The ALU provides one 8 bit result output (Y) an overflow flag (OVER) and a done flag (DONE). A table of the ALU's supported operations is given in table 1. A diagram of the inputs and outputs is shown in figure 1. A description of the function of each bus/pin is given in table 2.

Operation	Opcode	Clock Cycles	Overflow Condition	Description
A pass	0x0	1	N/A	Passes A to Y unmodified
B pass	0x1	1	N/A	Passes B to Y unmodified
Bitwise AND	0x2	1	N/A	Y is bitwise AND combination of operands A and B
Bitwise OR	0x3	1	N/A	Y is bitwise OR combination of operands A and B
Bitwise XOR	0x4	1	N/A	Y is bitwise XOR combination of operands A and B
Addition	0x5	1	$A + B > 255$	Y is the sum of operands A and B
Subtraction	0x6	1	$A + (\bar{B} + 1) > 255$	Y is the sum of A and the 2's complement inverse of B
Multiplication	0x7	9	$A * B > 255$	Y is the product of A and B

Table 1: Table of supported operations

Figure 1: ALU Inputs and Outputs

Bus / Pin	Width (Bits)	Function
Input		
A	8	First 8-Bit operand - input to mathematical or logical operation.
B	8	Second 8-Bit operand - input to mathematical or logical operation.
OP	3	Opcode - selects which operation to perform.
RST_N	1	Active low asynchronous reset - puts the ALU into initial ready state.
EN	1	Enable - starts ALU when high if in ready state. Must be high for ALU to output data.
Output		
Y	8	8 Bit result - output of the ALU operation
OVER	1	Overflow flag - high value generally indicates result cannot be represented in bits of Y. Exact meaning can vary between operations.
DONE	1	Is low while operation is in progress or ALU is ready, high when operation is completed.

Table 2: ALU IO Functional Descriptions

1.1 ALU Operation

Before beginning an operation the ALU must be reset by setting RST_N low, after reset occurs the ALU is considered to be in the "ready" state. EN must be low for all rising edges of CLK while the ALU is in the ready state. Once the inputs on A, B, and OP are stable, EN can be set high to begin ALU operation. The rising edge of EN must occur when CLK is low. EN must remain high until after the next falling edge of CLK. At this point the ALU enters the "running" state. From this point on the value of EN can be changed without effecting the ALU (or the result when the ALU is done). The ALU will always output all zeros when EN is low. When DONE goes high the ALU is in the "done" state. The operation is finished, and results can be read from Y, and OVER. A timing diagram of a normal ALU operation is shown in figure 2.

Figure 2: ALU Operation Timing Diagram

2 Design and Implementation

This ALU is designed to utilize modular operations, to allow the design to allow for easy testing during the design process, and potential rapid addition of new functions in the future. These modular operations are then linked together with integrated together with structures to allow for the selection of operations, forming the complete ALU.

2.1 Operation Modules

Each operation module accepts the inputs, and supplies the outputs shown in table 3. All outputs of the modules are routed through tristate buffers - the outputs of an operation are floating unless its enable pin is high.

There are two primary types of operation modules utilized in this ALU, combinational logic operations, and sequential logic operations. For combinational logic operations, the CLK and RST_N inputs are not needed, and DONE is always high when the module is enabled. A diagram of such an operation module is shown in figure 3. Sequential logic operations utilize all inputs to perform operations that require more than one clock cycle. The only such operation in this ALU is multiplication. A diagram of this type of module is shown in 4.

The following sections will include a brief description of the implementation of each ALU operation, and a listing of its SystemVerilog code.

2.1.1 A Pass

A Passthrough passes the 8-bit operand A to the output Y without modification. In the case enable is low, all outputs float to Z.

Figure 3: Schematic of a Combinational Operation Module

Figure 4: Schematic of a Sequential Operation Module

Listing: a_pass.sv

```

1  /*
2  Project: 8-Bit ALU
3  Author: John O'Connor
4  Sources: N/A
5
6  Module for A passthrough
7  */
8
9  module A_pass(
10     input logic [7:0] A,
11     input logic enable,
12     output logic [7:0] Y,
13     output logic done,
14     output logic overflow
15
16 );

```

Bus / Pin	Width (Bits)	Function
Input		
A	8	First 8-Bit operand - input to operation.
B	8	Second 8-Bit operand - input to operation.
RST_N	1	Active low asynchronous reset - resets the module to initial ready state.
EN	1	Enable - enables the module. The module will only output data when this pin is high
Output		
Y	8	8 Bit result - output of the operation
OVER	1	Overflow flag - high value generally indicates result cannot be represented in bits of Y. Exact meaning can vary between operations.
DONE	1	Is low while operation is in progress or is ready, high when operation is completed.

Table 3: Operation Module IO Descriptions

```

17
18     assign Y = enable ? A : 8'bz; //Assigns Y when enable is high
19     assign done = enable ? 1'b1 : 1'bz; // Done is high when enable is high
20     assign overflow = enable ? 1'b0 : 1'bz; // No overflow occurs for passthrough
21
22
23
24 endmodule

```

2.1.2 B Pass

B Passthrough passes the 8-bit operand B to the output Y without modification. In the case enable is low, all outputs float to Z.

Listing: b_pass.sv

```

1  /*
2  Project: 8-Bit ALU
3  Author: John O'Connor
4  Sources: N/A
5
6  Module for B passthrough
7  */
8
9  module B_pass(
10     input logic [7:0] B,
11     input logic enable,

```

```

12     output logic [7:0] Y,
13     output logic done,
14     output logic overflow
15 );
16
17     assign Y = enable ? B : 8'bz; //Assigns Y when enable is high
18     assign done = enable ? 1'b1 : 1'bz; // Done is high when enable is high
19     assign overflow = enable ? 1'b0 : 1'bz; // No overflow occurs for passthrough
20
21
22 endmodule

```

2.1.3 Bitwise AND

Bitwise AND performs the logical AND operation on each corresponding bit of the operands A and B, setting the result of this to Y. A bit in Y is 1 if and only if the corresponding bits in A and B are both 1. When enable is low, all outputs float.

Listing: bw_and.sv

```

1  /*
2  Project: 8-Bit ALU
3  Author: Max Fabian
4  Sources: N/A
5
6  Module for running the Bitwise AND in the ALU
7  */
8  module Bitwise_AND(
9      input logic [7:0] A, B, //8-bit Operand inputs
10     input logic enable,      //Enable - sets output of operator to floating
11     output logic [7:0] Y,    //8-bit Output
12     output logic done,       //Done Flag
13     output logic overflow    //Overflow Flag
14 );
15
16     //Assigns Y to the output of Bitwise AND when enable is high
17     assign Y = enable ? (A & B) : 8'bz;
18
19     //Simple Functions like this one have simple done and overflow flags
20     assign done      = enable ? 1'b1      : 1'bz;
21     assign overflow  = enable ? 1'b0      : 1'bz;
22
23 endmodule

```

2.1.4 Bitwise OR

Bitwise OR performs the logical OR operation on each corresponding bit of the operands A and B, setting the result of this to Y. A bit in Y is 1 if either or both corresponding bits in A and B are 1. When enable is low, all outputs float.

Listing: bw_or.sv

```
1  /*
2  Project: 8-Bit ALU
3  Author: Max Fabian
4  Sources: N/A
5
6  Module for running the Bitwise OR in the ALU
7  */
8  module Bitwise_OR (
9      input logic [7:0] A, B, //8-bit Operand inputs
10     input logic enable,      //Enable - sets output of operator to floating
11     output logic [7:0] Y,     //8-bit Output
12     output logic done,        //Done Flag
13     output logic overflow     //Overflow Flag
14 );
15
16     //Assigns Y to the output of Bitwise OR when enable is high
17     assign Y = enable ? (A | B) : 8'bz;
18
19     //Simple Functions like this one have simple done and overflow flags
20     assign done = enable ? 1'b1:1'bz;
21     assign overflow = enable ? 1'b0:1'bz;
22
23 endmodule
```

2.1.5 Bitwise XOR

Bitwise XOR performs the logical XOR operation on each corresponding bit of the operands A and B, setting the result of this to Y. A bit in Y is 1 if either the of the corresponding bits in A or B is 1 but both. When enable is low, all outputs float.

Listing: bw_xor.sv

```
1  /*
2  Project: 8-Bit ALU
3  Author: John O'Connor
4  Sources: N/A
5
6  Module for Bitwise XOR.
7  */
8
9  module Bitwise_XOR (
10     input logic [7:0] A, B,
11     input logic enable,
12     output logic [7:0] Y,
13     output logic done,
14     output logic overflow
15 );
16
17
18     assign Y = enable ? (A ^ B) : 8'bz; // Assigns Y when enable is high, otherwise Y is
    ↪ floating
```

```

19     assign done = enable ? 1'b1 : 1'bz; // Done is high when enable is high
20     assign overflow = enable ? 1'b0 : 1'bz; // No overflow occurs with bitwise XOR
21
22 endmodule

```

2.1.6 Addition

Addition performs unsigned addition on two 8-bit operands A and B, setting the result of this to Y. In the case where the result of $A + B$ exceeds 255, overflow will be set to 1, representing the most significant bit. When enable is low, all outputs float.

Listing: addition.sv

```

1  /*
2  Project: 8-Bit ALU
3  Author: Max Fabian
4  Sources: N/A
5
6  Module for running the adder in the ALU
7  */
8  module Addition(
9      input logic [7:0] A, B, //8-bit operand inputs
10     input logic enable,      //Enable - sets output of operator to floating
11     output logic [7:0] Y,    //8-bit output
12     output logic overflow,   //Overflow Flag
13     output logic done        //Done Flag
14 );
15     //Assigns overflow as 9th bit to Y and takes adder when enable is high
16     assign {overflow, Y} = enable ? (A + B) : 9'bz;
17
18     //Done flag on enable high
19     assign done = enable ? 1'b1:1'bz;
20
21 endmodule

```

2.1.7 Subtraction

Subtraction performs unsigned subtraction on two 8-bit operands A and B, setting the result of this to Y. This implementation uses the two's complement of B and computes subtraction by adding A to the two's complement of B. When enable is low, all outputs float.

Listing: subtraction.sv

```

4  Sources: N/A
5
6  Module for running the Subtractor in the ALU

```

```

7  */
8  module Subtraction (
9      input logic [7:0] A, B, //8-bit Operand inputs
10     input logic enable,      //Enable - sets output of operator to floating
11     output logic [7:0] Y,     //8-bit Output
12     output logic done,        //Done Flag
13     output logic overflow     //Overflow Flag
14 );
15
16     //Assigns Y to the output of a subtractor when enable is high
17     assign Y = enable ? (A - B) : 8'bz;
18
19     //Simple Functions like this one have simple done and overflow flags
20     assign done = enable ? 1'b1:1'bz;
21     assign overflow = enable ? 1'b0:1'bz;
22
23 endmodule

```

2.1.8 Multiplication

Multiplication performs a binary sequential multiplication by running for 9 clock cycles for 8 cycles the value for A has a logical left shift applied and is added to the result register if the equivalent bit in B is high. This functions similarly to writing out long multiplication by hand. The schematic is shown in Figure 5. This can also be modeled as a state machine with 3 states, an initial state,

Figure 5: Schematic of the Multiplication Module

multiplication state, and an finished state. Where the initial state sets the registers to their reset state, sending to the multiplication state. The multiplication state shifts the multiplicand and adds it to the result when conditions are met, and re-enters the multiplication state until it has completed this state 8 times, exiting to the final state. The final state sets the done flag high and sets the output and overflow accordingly. This can be visualized in Figure 6.

Figure 6: State Machine Diagram for the Multiplication Module

64             i <= i + 1;
65
66             //Once the loop has finished the result can be thrown to
67             // the outputs, and the done flag can be raised so the ALU
68             // knows the operation has concluded.
69         end else begin
70             {cout, Y} = result;
71             //Since the output of a multiplier is 2x number of
72             // input bits and our output is staying at 8 bits
73             // the overflow flag needs to be raised whenever
74             // the result exceeds 8 bits
75
76             if(cout > 0) begin
77                 overflow <= 1;
78             end else begin
79                 overflow <= 0;
80             end
81
82             //Raising the done flag should always be the last
83             // thing it does
84             done <= 1'b1;
85         end
86     end
87 end
88
89 endmodule
90
91

```

2.2 ALU Utility Modules

Three SystemVerilog modules were developed to be used within ALU operations or the ALU itself. These include a variable width asynchronously resettable register with enable, a 3 bit multiplexer with enable, and a variable width counter. The Implementation details and SystemVerilog listings for these modules are provided in the subsequent sections.

2.2.1 Opcode Decoder

The decoder takes a 3-bit opcode input and converts it to an 8-bit, one-hot signal used to enable a given operation module. When enable is low, all outputs are set to 0.

Listing: multiplexer_3_en.sv

```
1  /*
2  Project: 8-Bit ALU
3  Author: Nolan Kessler
4
5  Implements a three bit multiplexer with enable
6  */
7
8  module Decoder (
9      input logic [2 : 0] in,
10     input logic enable, //Output of multiplexer is 0 unless enable is high.
11     output logic [7 : 0] out
12 );
13     always_comb begin
14         if (enable) begin
15             case (in)
16                 3'b000: out = 8'b0000_0001;
17                 3'b001: out = 8'b0000_0010;
18                 3'b010: out = 8'b0000_0100;
19                 3'b011: out = 8'b0000_1000;
20                 3'b100: out = 8'b0001_0000;
21                 3'b101: out = 8'b0010_0000;
22                 3'b110: out = 8'b0100_0000;
23                 3'b111: out = 8'b1000_0000;
24             endcase
25         end
26         else begin
27             out = 4'b0;
28         end
29     end
30 endmodule
```

2.2.2 Variable Width Register

The variable width register is a configurable register, with a default width of 1, used to store the value of the in signal. If enable is high, the input "in" is copied to the output on the rising clock edge. Then, when enable is low, the register holds the value of out. If reset goes low, the output is immediately set to 0.

Listing: decoder.sv

```
1  /*
2  Project: 8-Bit ALU
3  Author: Nolan Kessler
4  Sources: Based on my register implementation from Lab 5
5
6  Implements a parameterized width register with enable and active low reset.
7  */
8
9  module Register_en_rstn #(parameter WIDTH = 1) (
10     input logic clk,
11     input logic enable, //Enable - copy in to out on rising edge of clk only when high
12     input logic rst_n, //Active low reset - set out to zero on falling edge
13     input logic [WIDTH - 1 : 0] in,
14     output logic [WIDTH - 1 : 0] out
15 );
16
17     always_ff @(posedge clk, negedge rst_n) begin
18
19         if (rst_n == 0) begin
20             out <= 0;
21         end
22
23         else begin
24             if (enable != 0) begin
25                 out <= in;
26             end
27         end
28
29     end
30
31 endmodule
```

2.2.3 Counter

The counter is an N width counting module with a default width of 4 bits. On the rising clock edge, the counter increments itself by the value of addBy. If reset is high, the counter resets the count to 0.

Listing: counter.sv

```
1  /*
2  Project: 8 Bit ALU
3  Author: Nolan Kessler
4  Sources: Based on my counter implementation from lab 5
5
6  A configurable counter
7  */
8
9  module Counter
10     #(
```

```

11 parameter IN_WIDTH = 4,
12 parameter OUT_WIDTH = 4
13 )
14 (
15     input logic clock,
16     input logic reset_n,
17     input logic enable,
18     input logic [IN_WIDTH-1:0] addBy,
19     output logic [OUT_WIDTH-1:0] count
20 );
21
22 logic [OUT_WIDTH-1:0] count_next;
23
24 always_comb begin
25     count_next = count + (addBy & {IN_WIDTH{enable}});
26 end
27
28 Register_en_rstn #(OUT_WIDTH) register(
29     .clk(clock),
30     .rst_n(reset_n),
31     .in(count_next),
32     .out(count),
33     .enable(1'b1)
34 );
35
36 endmodule

```

2.3 ALU Implementation

A schematic diagram of the full ALU is shown in figure 7. Four registers are used to ensure that the inputs to the ALU remain consistent throughout the entire operation. R_a , R_b , and R_{op} will store the inputs to the ALU on the first rising clock edge that occurs while EN is high. The output of the locking register R_{lk} becomes high on the next clock falling edge, disabling further updates to A, B, and OP, and enabling the decoder, which will select the requested function. At this point the value of EN can be changed without impacting the ALU operation.

Figure 7: Schematic of Full ALU

3 Project Reflection

Implementing the project overall went well. Implementing each individual combinational module and getting them working in the larger ALU module was quick and relatively simple. However we ran into some complications when attempting to implement a more complicated sequential module. This was the multiplication module. Since it required multiple clock cycles to perform, the module needed to have proper timing and a comparator to track the current clock cycle the system is on and run the system accordingly. We ran into a few issues with the done and overflow registers being out of sync causing the module to fail to properly output the overflow flag. These smaller difficulties were more time consuming than difficult as they were small errors that required

looking over the HDL script and RTL Viewer to identify where the timing issues would occur.

4 Design Verification

Design verification is done using SystemVerilog test benches. Each operation module has its own test bench to test expected values compared to simulated. The ALU itself has its own test bench which ensures the ALU design and utility modules function as expected.

4.1 Operation Test Benches

Each operation module has a test bench. All test benches with the exception of the multiplication test bench test all possible combinations of operands as well as testing the case where the enable signal is low.

4.1.1 A Pass

4.2 ALU Test Bench

The ALU test bench tests the ALU design as well as the functionality of the utility modules. It iterates through each operation by testing one opcode at a time, resetting between tests.

Listing: alu.tb.sv

```
1 module ALU_tb;
2     //inputs
3     logic      en;
4     logic      clk;

ALU Testbench Waveform

We can analyze the ALU test bench's waveform using the waveform

Figure 8: Waveform Generated by ALU Test Bench

5 Hardware Validation

6 Reflection on Design Process

Implementing the project overall went well. Implementing each individual combinational module and getting them working in the larger ALU module was quick and relatively simple. However we ran into some complications when attempting to implement a more complicated sequential module. This was the multiplication module. Since it required multiple clock cycles to perform, the module needed to have proper timing and a comparator to track the current clock cycle the system is on and run the system accordingly. We ran into a few issues with the done and overflow registers being out of sync causing the module to fail to properly output the overflow flag. These smaller difficulties were more time consuming than difficult as they were small errors that required looking over the HDL script and RTL Viewer to identify where the timing issues would occur.
